

ATPG run to generate bypass patterns :-

- EDT coverage is slightly less when compared to bypass.

REASON:- Through LFSR and phase shifter logic, the tool might not be able to generate some patterns which will detect some faults.

But in bypass mode, it will be able to generate those patterns.

POSSIBILITY OF GETTING CONFUSED :-

If we check in the log file, we feel that EDT cov is more than bypass.

That is because the no. of faults in EDT run is more than no. of faults in bypass.

Eg:- bypas - 100 faults
① 90 - detected
cov = 90%.

EDT - 200 faults
185 - detected
cov = 92.5%.

In bypas only 10 faults are not detected. But in EDT, 15 faults are not detected.

Eg②:- bypas - 100 faults
90 - detected
cov = 90%.

EDT - 200 faults
180 - detected
cov = 90%.

In bypas only 10 faults are not detected. But in EDT, 20 faults are not detected.

In reality EDT cov is slightly less than the bypas cov.
